To characterize the physiology of RGCs and to reveal the long-term effects of electroretinographic (ERG) electric pulse exposure on the survival of retinal ganglion cells (RGCs) in rabbits from postnatal (P) day 0 to postnatal day 12. Single- and double-pulse ERGs were recorded at P0, P2, P3, P4, P5, P6, P7, P8, P9 and P10, and the retinas from these animals were used to investigate the survival of RGCs. Changes in the morphology of a single RGC were observed. Optical micrographs of retinas taken at P2 and P6 were used to examine the retinocortical projection. The morphology of the RGCs at P2 and P6 was normal. At P8 and P10, the RGCs could not be identified by morphology or by retrograde labelling and retinal sections. Among a total of 489 RGCs at P2, 331 (68.7%) survived at P6. In 248 RGCs at P8, 186 (75.4%) survived at P10. At the earliest recording time point of 2 days, the survival rates of RGCs in response to single-pulse exposure were 29.4%, 15.3%, 26.5%, 26.6% and 9.3% at P3, P4, P5, P
